

# Efficient Formally Secure Compilers to a Tagged Architecture

Cătălin Hrițcu

Inria Paris

# Computers are insecure

- **devastating low-level vulnerabilities**
- **programming languages, compilers, and hardware architectures**
  - designed in an era of scarce hardware resources
  - too often trade off security for efficiency
- **the world has changed (2016 vs 1972)**
  - security matters, hardware resources abundant
  - time to revisit some tradeoffs

# Hardware architectures

- **Today's processors are mindless bureaucrats**

- “write past the end of this buffer”
- “jump to this untrusted integer”
- “return into the middle of this instruction”

- **Software bears most of the burden for security**

- **Manufacturers have started looking for solutions**

- 2015: Intel Memory Protection Extensions (MPX)  
and Intel Software Guard Extensions (SGX)
- 2016: Oracle Silicon Secured Memory (SSM)

“Spending silicon to improve security”

# Unsafe low-level languages

- C (1972) and C++ **undefined behavior**
  - including buffer overflows, checks too expensive
  - compilers optimize aggressively assuming undefined behavior will simply not happen

- **Programmers bear the burden for security**
  - just write secure code ... all of it

[PATCH] CVE-2015-7547 --- **glibc**  
**getaddrinfo() stack-based buffer overflow**

**DNS queries**

hell" <carlos at redhat dot com>

• **Date:** Tue, 16 Feb 2016

• **Subject:** [PATCH] CVE-2015-7547: glibc: getaddrinfo() stack-based buffer overflow

• **Authentication-results:** sourceware.org; auth=none

• **References:** <56C32C20 dot 1070006 at redhat dot com>

**vulnerable since May 2008**

The glibc project thanks the Google Security Team and Red Hat for reporting the security impact of this issue, and Robert Holiday of Ciena for reporting the related bug 18665.

# Safer high-level languages

- **memory safe** (at a cost)
- **useful abstractions** for writing secure code:
  - GC, type abstraction, modules, immutability, ...
- **not immune to low-level attacks**
  - large runtime systems, in C++ for efficiency
  - **unsafe interoperability with low-level code**
    - libraries often have large parts written in C/C++
    - **enforcing abstractions all the way down too expensive**

OCaml

Haskell

# Efficient Secure Compilation to Micro-Policies

2<sup>nd</sup> part of this talk (more speculative)

1. Secure semantics for low-level languages
2. Secure interoperability with lower-level code
  - Formally: **fully abstract compilation**
    - holy grail, enforcing abstractions all the way down
    - **currently this would be way too expensive**

- **Key enabling technology: micro-policies**
  - hardware-accelerated tag-based monitoring

1<sup>st</sup> part of this talk

# MICRO-POLICIES

# Micro-Policies team

- Formal methods & **architecture** & systems
- Current team:
  - *Inria*: Cătălin Hrițcu, Yannis Juglaret
  - *UPenn*: Arthur Azevedo de Amorim, **André DeHon**, Benjamin Pierce, **Nick Roessler**, Antal Spector-Zabusky
  - *Portland State*: Andrew Tolmach
  - *MIT*: Howard E. Shrobe, Stelios Sidiroglou-Douskos
  - *Industry*: Draper Labs, Bluespec Inc
- Spinoff of past project:  
DARPA CRASH/SAFE (2011-2014)

D R A P E R

bluespec®

# Micro-policies

- add **large tag** to each machine word **unbounded metadata**

- words in memory and registers are all tagged

<b>pc</b>	<b>tag</b>
<b>r0</b>	<b>tag</b>
<b>r1</b>	<b>tag</b>
<b>r2</b>	<b>tag</b>

<b>mem[0]</b>	<b>tag</b>
<b>mem[1]</b>	<b>tag</b>
<b>mem[2]</b>	<b>tag</b>
<b>mem[3]</b>	<b>tag</b>

\*Conceptual model, our hardware implements this efficiently

# Tag-based instruction-level monitoring

pc	tpc
r0	tr0
r1	tr1
r2	tr2

mem[0]	tm0
mem[1]	tm1
mem[2]	tm2
mem[3]	tm3

decode(mem[1]) = add r0 r1 r2

add

allow

# Tag-based instruction-level monitoring

pc	tpc
r0	tr0
r1	tr1
r2	tr2

mem[0]	tm0
mem[1]	tm1
mem[2]	tm2
mem[3]	tm3

← pc  
← r0

decode(mem[1]) = store r0 r1

store

**disallow** → **bad action stopped!**

# Micro-policies are cool!

- **low level + fine grained**: unbounded per-word metadata, checked & propagated on each instruction
- **expressive**: can enforce large number of policies
- **flexible**: tags and monitor defined by software
- **efficient**: accelerated using hardware caching
- **secure**: simple enough to formally verify security
- **real**: FPGA implementation on top of RISC-V CPU

# Expressiveness

- information flow control (IFC) [Oakland'13, POPL'14]
- monitor self-protection
- compartmentalization
- dynamic sealing

Verified  
(in Coq)   
[Oakland'15]

- heap memory safety
- code-data separation
- control-flow integrity (CFI)
- taint tracking
- ...

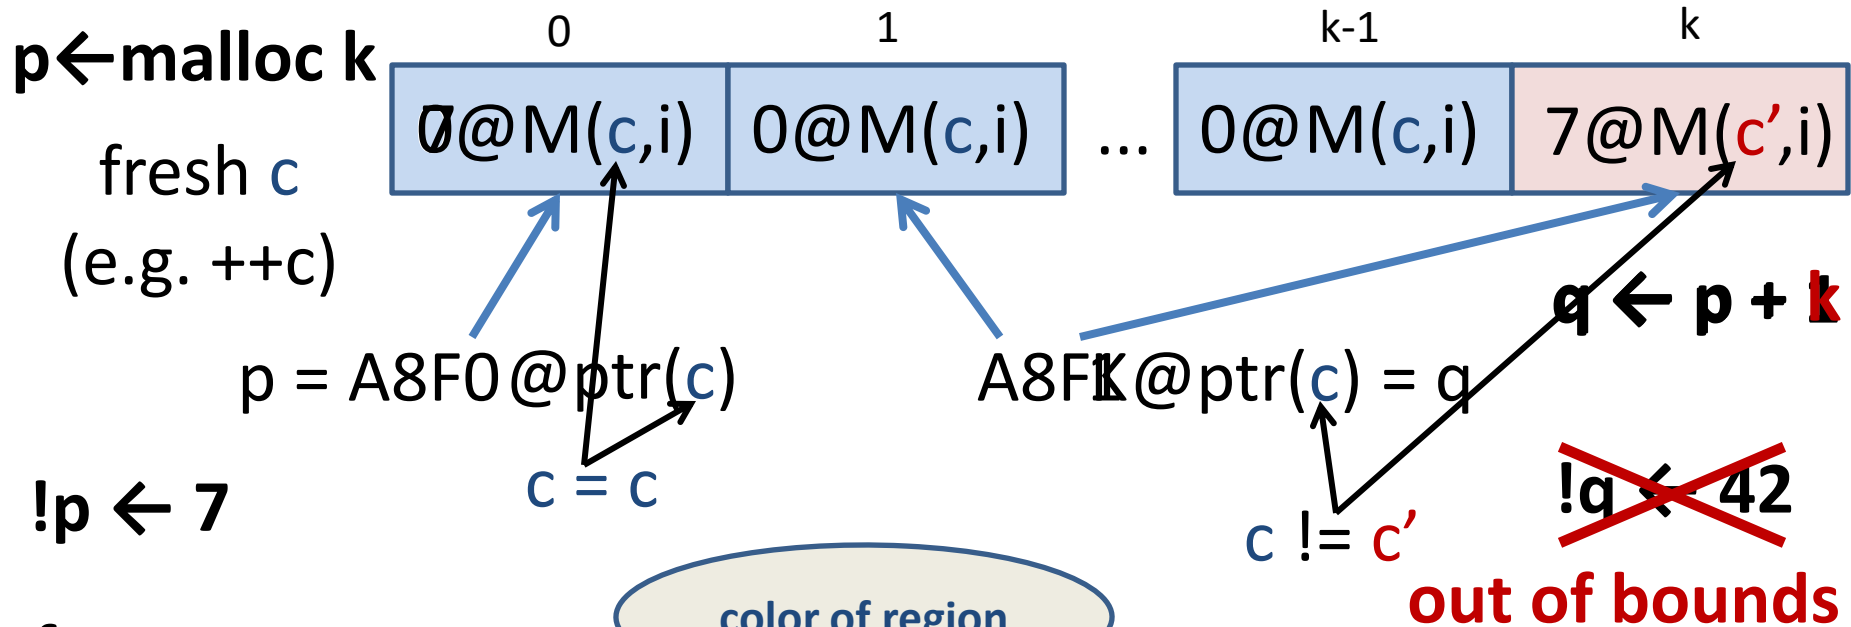

Evaluated  
(<10% runtime overhead)  
[ASPLOS'15]

# Flexibility (by example)

- **Heap memory safety** micro-policy prevents
  - **spatial violations**: reading/writing out of bounds
  - **temporal violations**: use after free, invalid free
  - for **heap-allocated data**
- Pointers become **unforgeable capabilities** 
  - can only obtain a valid pointer to a heap region
    - by allocating that region or
    - by copying/offsetting an existing pointer to that region

# Memory safety micro-policy

$!p \leftarrow 7$

$\text{free } p$

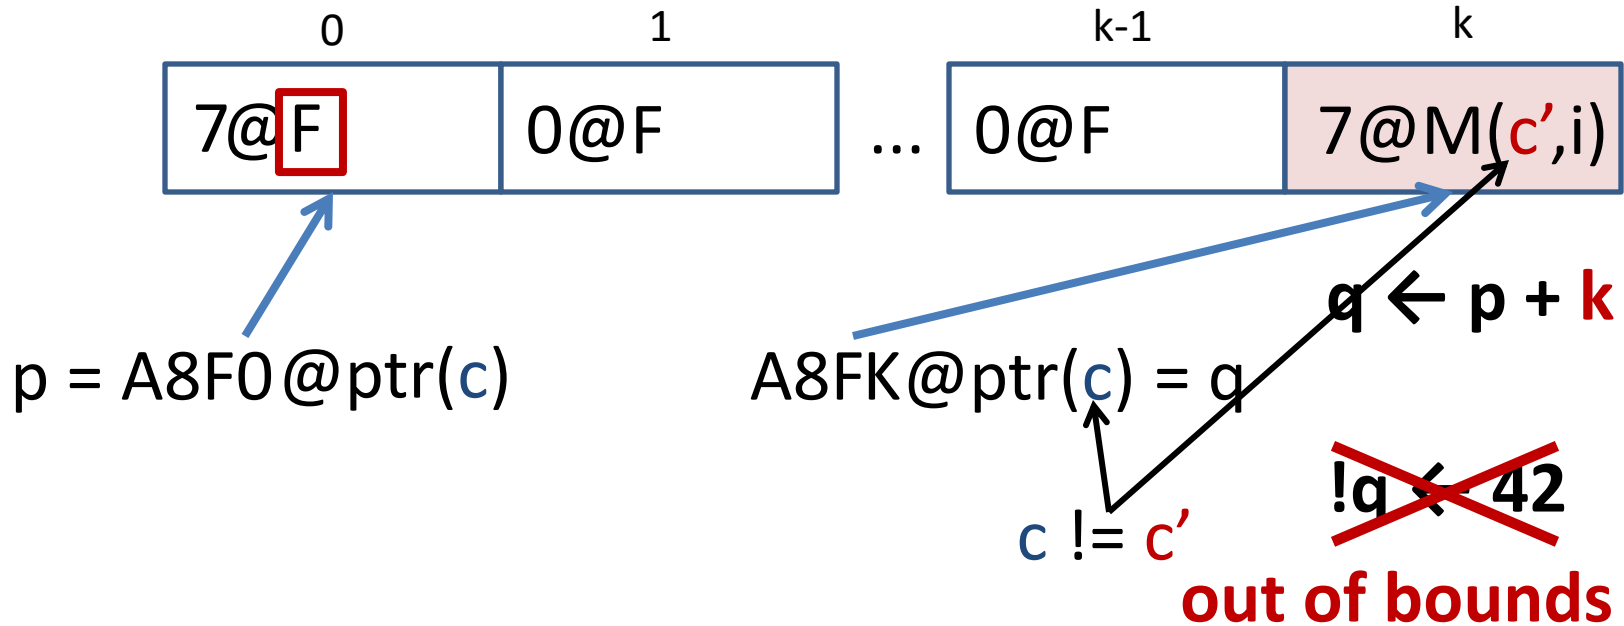

color of region

$T_v ::= i \mid \text{ptr}(c)$	tags on values
$T_m ::= M(c, T_v) \mid F$	tags on memory

color of region

tag of content

# Memory safety micro-policy

free p

~~$x \leftarrow !p$~~

**use after free**

$T_v ::= i \mid ptr(c)$	tags on values
$T_m ::= M(c, T_v) \mid F$	tags on memory

Intel MPX cannot detect this

Oracle Silicon Secured Memory (2016)  
 similar, but with only 16 colors

# Experimental evaluation (simulations)

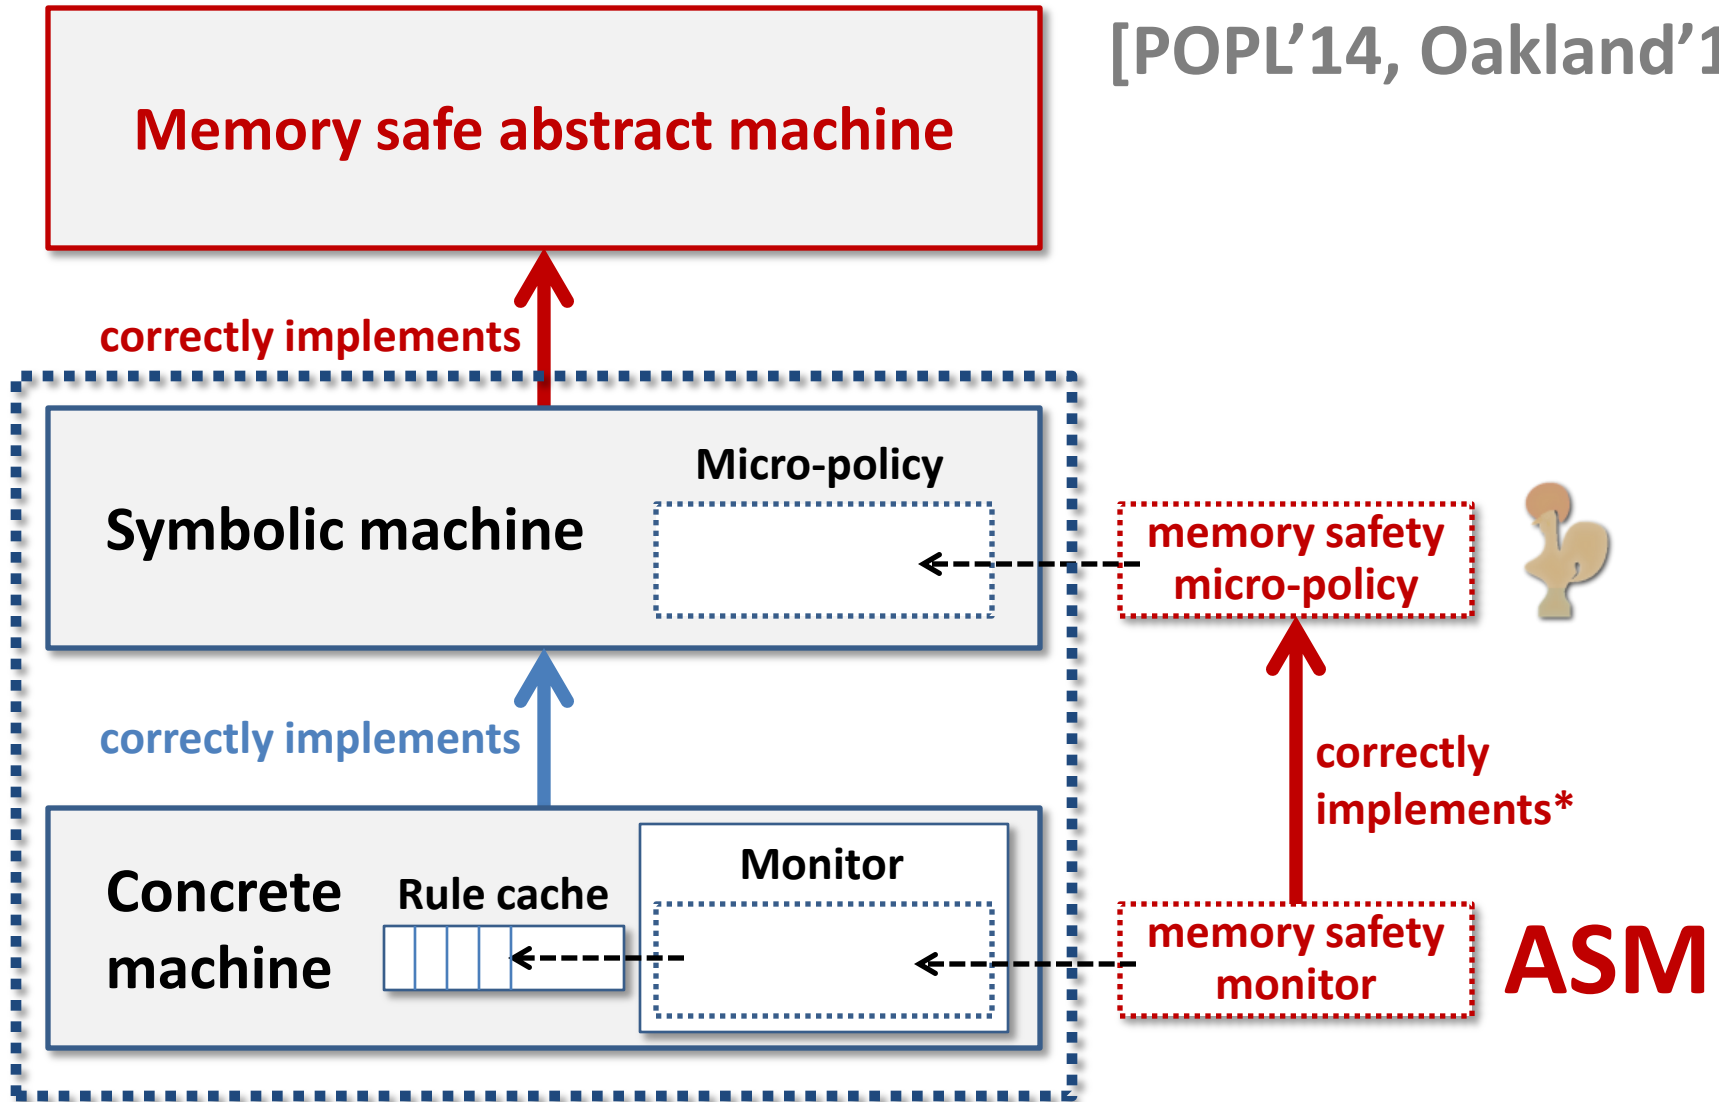

heap memory safety + code-data separation + taint tracking + control-flow integrity  
 simple RISC processor: single-core 5-stage in-order Alpha (pre RISC-V transition)

More details  
 [ASPLOS'15]

# Formal verification in Coq

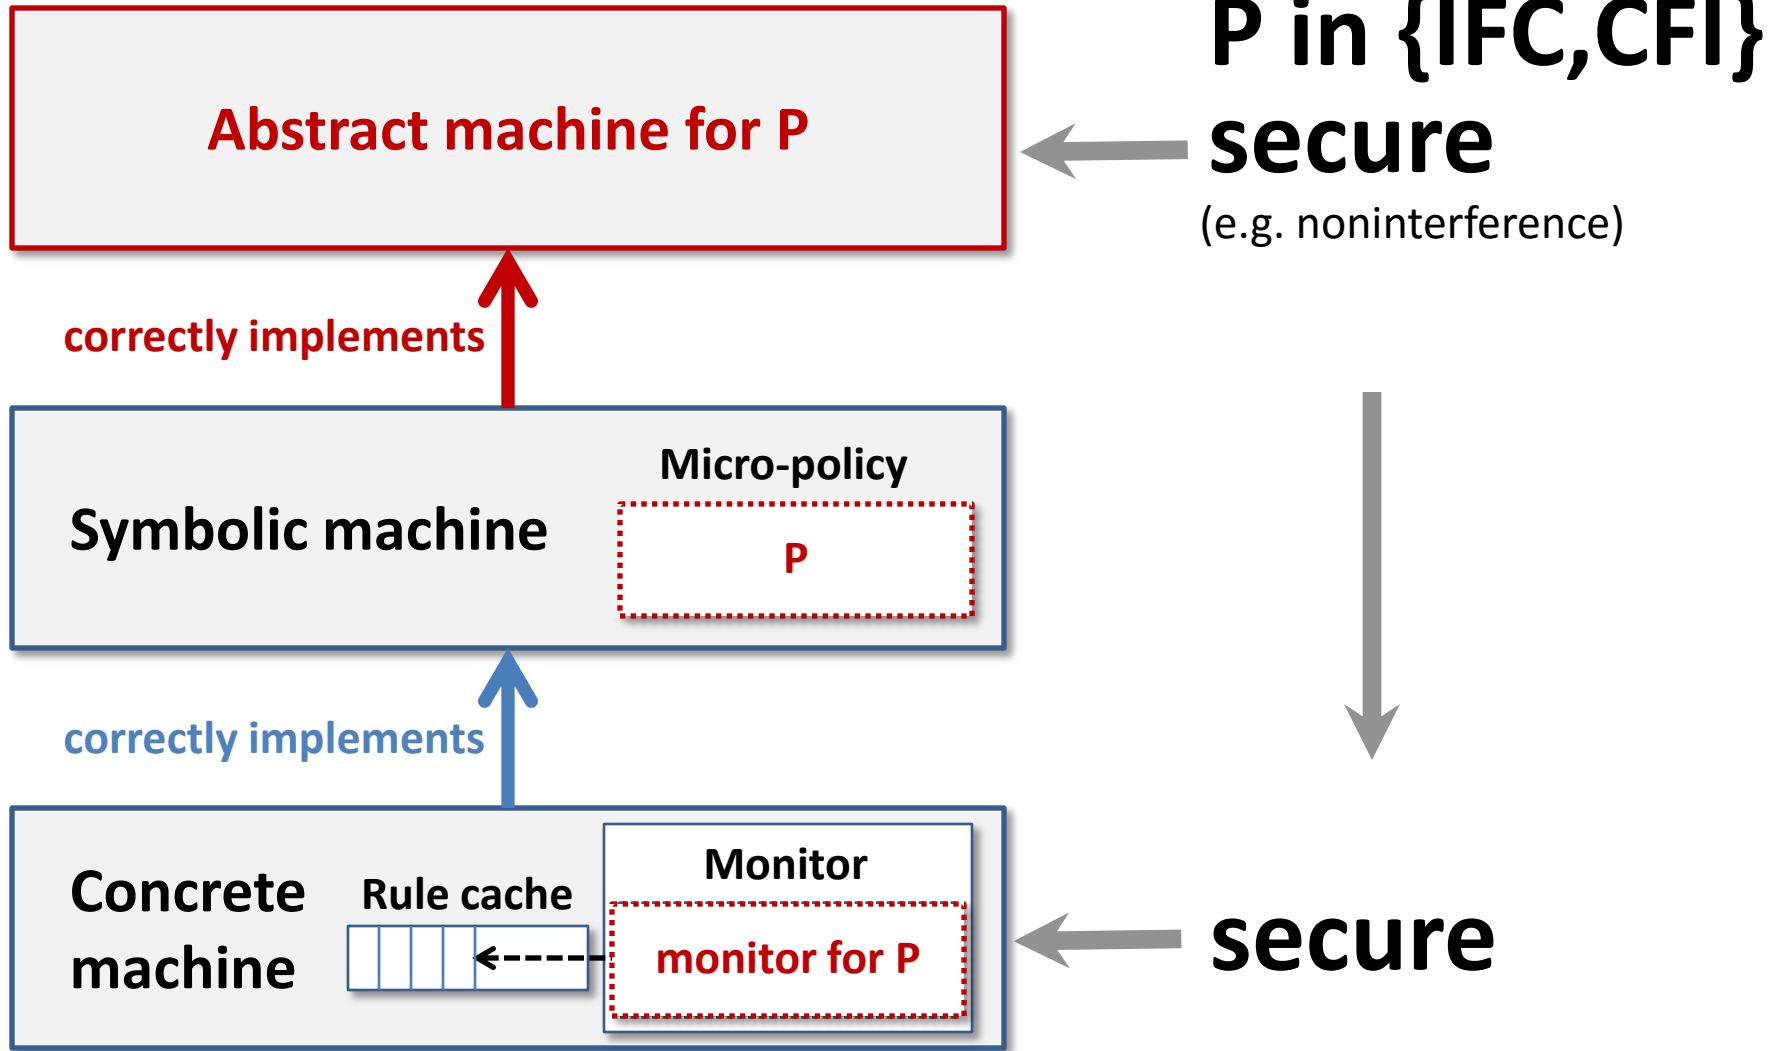

[POPL'14, Oakland'15]

**Generic Framework**

\*only proved for IFC  
(verified DSL compiler)

# Is this secure?

\* Working on **extrinsic definition of memory safety**

[Alpha is for address, Azevedo de Amorim et al, draft 2015]

# SECURE COMPILATION

Joint work with Yannis Juglaret

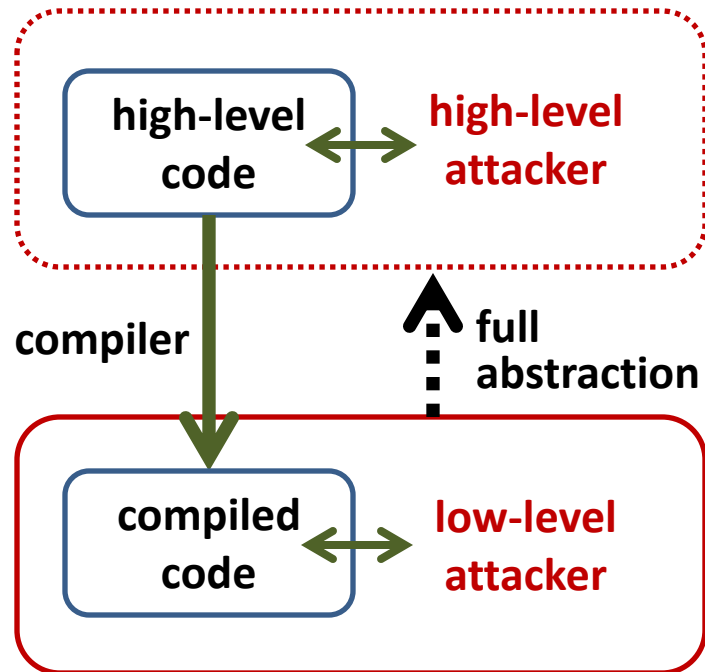

# Secure compilation

- **Goal:** to build the **first efficient secure compilers** for **realistic programming languages**
  - 1. Secure semantics for low-level languages**
    - C with memory safety and compartmentalization
  - 2. Secure interoperability with lower-level code**
    - ASM, C, ML, and F\* (verification system for ML)
    - problems are quite different at different levels
- Formally: **fully abstract compilation**
  - enforcing abstractions all the way down

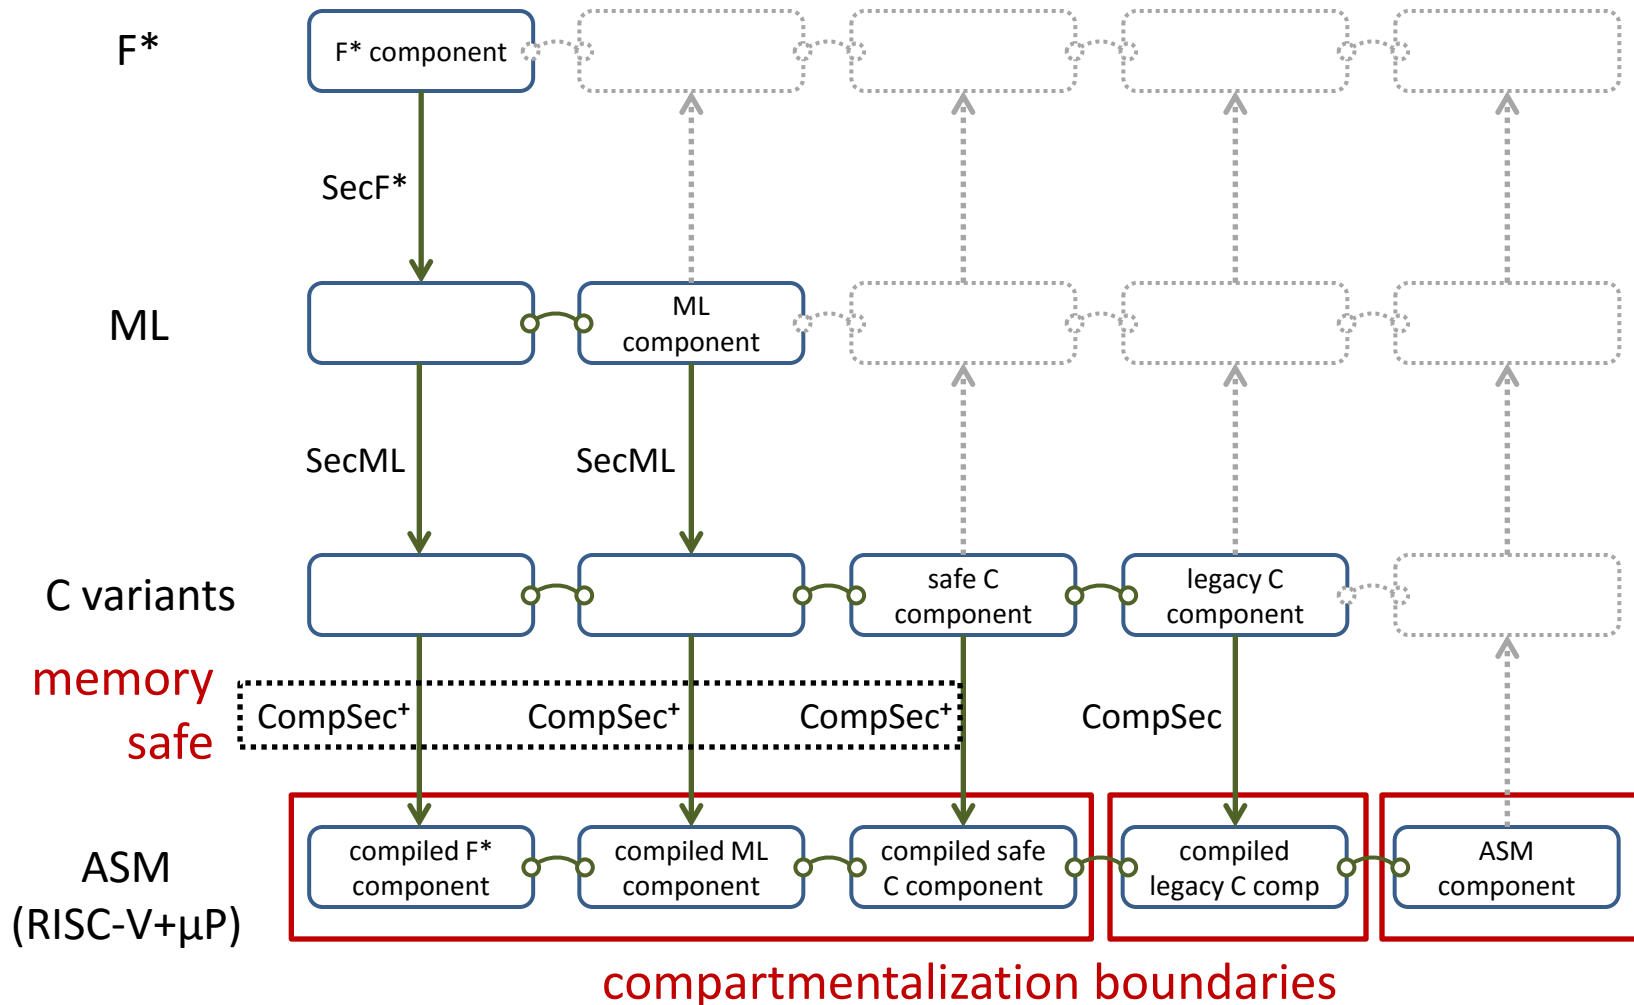

# Fully abstract compilation, intuition

**Benefits:** can reason about security in the source language;  
forget about compiler, linker, loader, runtime system,  
and (to some extent) low-level libraries

# Very long term vision

# Low-level compartmentalization

- Break up software into **mutually distrustful components** running with **minimal privileges** & interacting only via **well-defined interfaces**
- **Limit the damage** of control hijacking attacks to just the C or ASM components where they occur
- Not a new idea, already deployed in practice:
  - process-level privilege separation
  - software-fault isolation

- Micro-policies can give us **better interaction model**
- We also aim to **show security formally**

# Compartmentalized C

- Want to **add components with typed interfaces to C**
- Compiler (e.g. CompCert), linker, loader propagate interface information to low-level memory tags
  - each component's memory tagged with unique color
  - procedure entry points tagged with procedure's type
- Micro-policy enforcing:
  - **component isolation**
  - **procedure call discipline** (entry points)
  - **stack discipline for returns** (linear return capabilities)
  - **type safety** on cross-component interaction

[Towards a Fully Abstract Compiler Using Micro-Policies, Juglaret et al, TR 2015]

# Compartmentalization micro-policy

# Secure compartmentalization property

$\forall$  compromise scenarios.

$\forall$  low-level attack from compromised  $C_2 \downarrow, C_4 \downarrow, C_5 \downarrow$   
 $\exists$  high-level attack from some fully defined  $A_2, A_4, A_5$

follows from “structured full abstraction  
for unsafe languages” + “separate compilation”

[Beyond full abstraction, Juglaret, Hritcu, et al, draft'16]

# Protecting higher-level abstractions

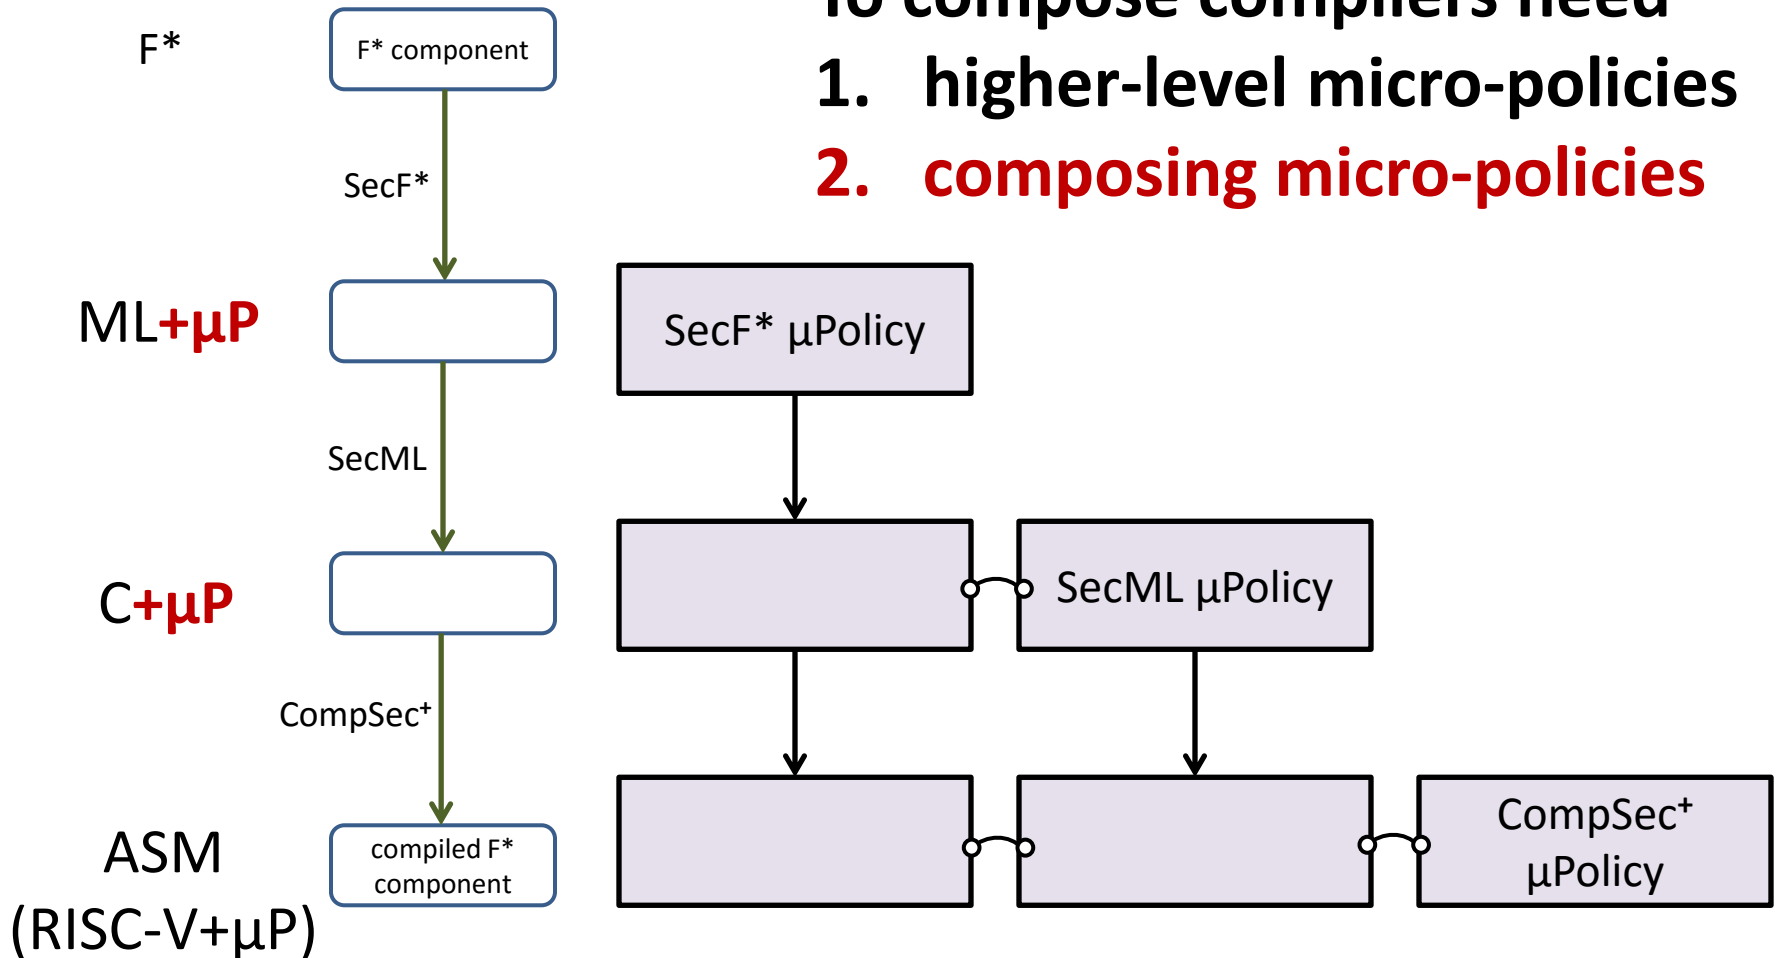

- **ML abstractions we want to enforce with micro-policies**
  - types, value immutability, opaqueness of closures, parametricity (dynamic sealing), GC vs malloc/free, ...
- **F\*: enforcing full specifications using micro-policies**
  - some can be turned into **contracts**, checked dynamically
  - fully abstract compilation of F\* to ML **trivial for ML interfaces** (because F\* allows and tracks effects, as opposed to Coq)
- **Limits of purely-dynamic enforcement**
  - functional purity, termination, relational reasoning
  - **push these limits further and combine with static analysis**

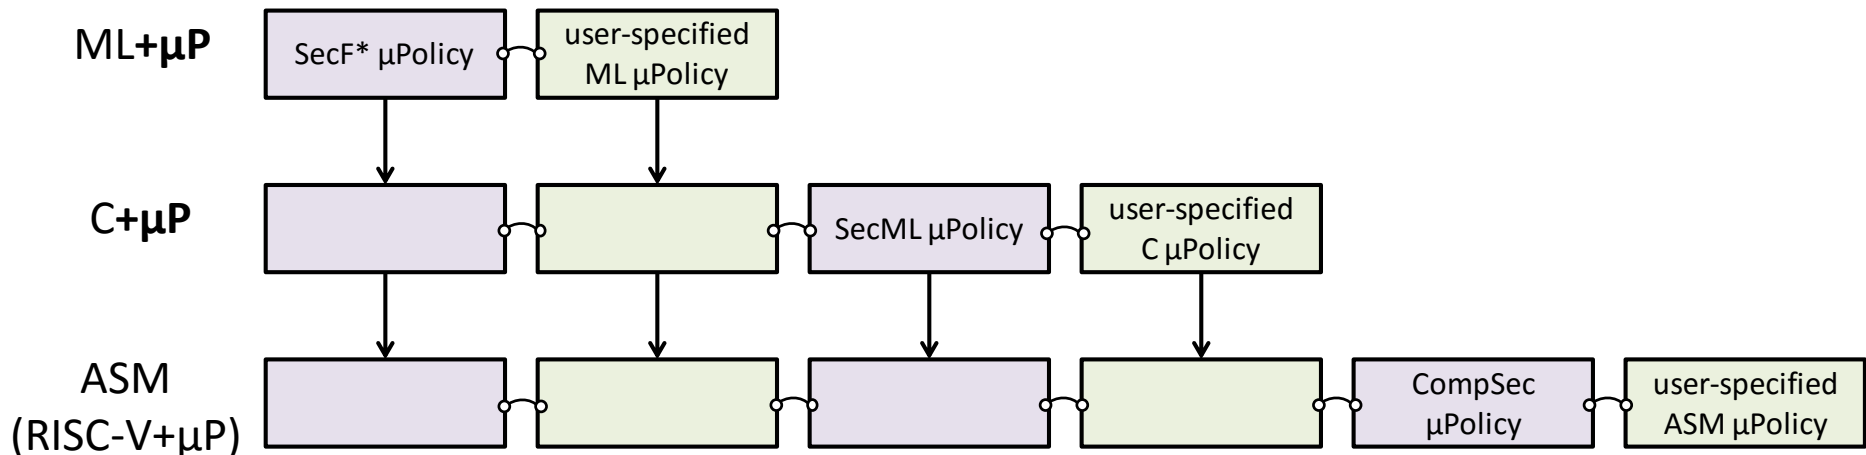

# Composing compilers and higher-level micro-policies

- To compose compilers need
1. higher-level micro-policies
  2. **composing micro-policies**

# User-specified higher-level policies

- By composing more micro-policies we can allow **user-specified micro-policies for ML and C**
- Good news: **micro-policy composition is easy** since tags can be tuples
- **But how do we ensure programmers won't break security?**
- **Bad news: secure micro-policy composition is hard!**

# Secure micro-policy composition

- **securely composing reference monitors is easy**
  - ... as long as they **can only stop execution**
- micro-policies have **richer interaction** model:
  - **monitor services**: malloc, free, classify, declassify, ...
  - **recoverable errors** are similar
- **composing micro-policies can break them**
  - e.g. composing anything with IFC can leak
  - memory safety + compartmentalization

# Secure compilation

- Solving conceptual challenges
  - **Secure micro-policy composition**
  - **Higher-level micro-policies** (for C and ML)
  - **Formalizing security properties** (i.e. attacker models)
- Building the first **efficient secure compilers** for **realistic programming languages**
  - C (CompCert): memory safety & compartmentalization
  - ML and F\*: protecting higher-level abstractions
- Measuring & lowering the cost of secure compilation
- Showing that these compilers are indeed secure
  - **Better verification and testing techniques**

- Redesigned ML verification system [POPL'16]
  1. **functional programming language with effects**  
(like OCaml, F#, Standard ML, Haskell)
  2. **deductive verification system based on SMT solvers**  
(like FramaC, Why3, Dafny, Boogie, VCC, ESC/Java2)
  3. **interactive proof assistant based on dependent types**  
(like Coq, Lean, Agda)
- Working on **language design, formal foundations, logical aspects, proof assistant, self-certification**
- Main practical application:
  - **verified reference implementation of upcoming TLS 1.3**

# Dependable property-based testing

- QuickCheck effective at finding bugs
- **reducing the testing effort**
  - language for property-based generators
- **obtaining stronger confidence**
  - polarized mutation testing
- **providing stronger formal foundations**
  - verified testing, generator synthesis(?)
- **integrating testing in proof assistants**
  - reducing the cost of interactive verification

# Conclusion

- **There is a pressing practical need for ...**
  - **more secure languages** providing strong abstractions
  - **more secure compiler chains** protecting these abstractions
  - **more secure hardware** making the cost of all this acceptable
  - **clear attacker models & strong formal security guarantees**
- Building the first **efficient secure compilers** for **realistic programming languages** (C, ML, F\*)
- **Targeting micro-policies** = new mechanism for hardware-accelerated tag-based monitors

**Thank you!**
